PICOQUANT

Webtalk February 2014

Please note ...

We at PicoQuant always try to present our latest findings to the scientific community as quickly as possible.

The creation of suited presentation material with in-depth information is, however, not always possible in a short time frame.

We have therefore decided that it would be beneficial to the scientific community to make our presentations or parts of presentations, that were given on conferences, available to the public. As a consequence, it might be possible that information is missing to understand all information included in a slide.

Thus, please don't hesitate to contact us in case you have any questions or need more information. We hope for your understanding and looking forward to hearing from you.

Your PicoQuant team

Fluorescence Correlation Spectroscopy (FCS) in Chemistry and Biology

Study of dynamic chemical or biomolecular processes causing fluctuations in the fluorescence intensity:

Exact determination of concentrations

- Molecular diagnostics
- Monitoring reaction kinetics

Molecular interactions

- Protein-protein interactions
- Association / dissociation processes
- Surface adsorption / desorption
- Complex formation, stoichiometry
- Formation of micelles (size, heterogeneity)
- Polymerization through monitoring viscosity

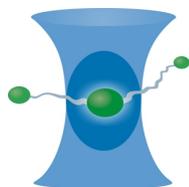

Diffusion behavior

- Folding / unfolding of proteins
- Lipid dynamics in model and cell membranes
- Hydrodynamic radius of complexes like molecules with their solvation shell

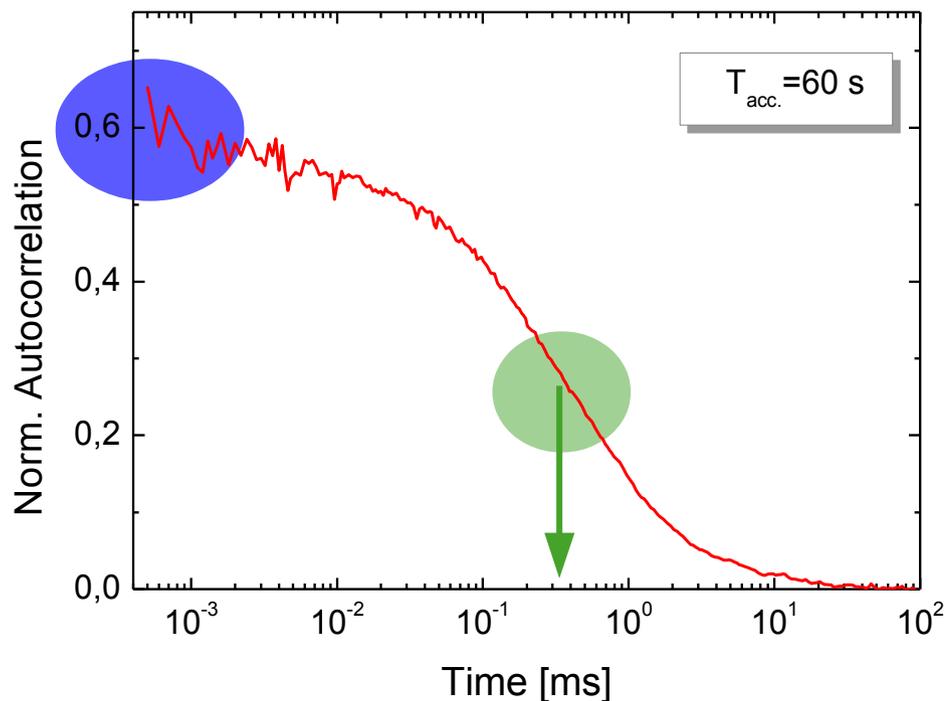

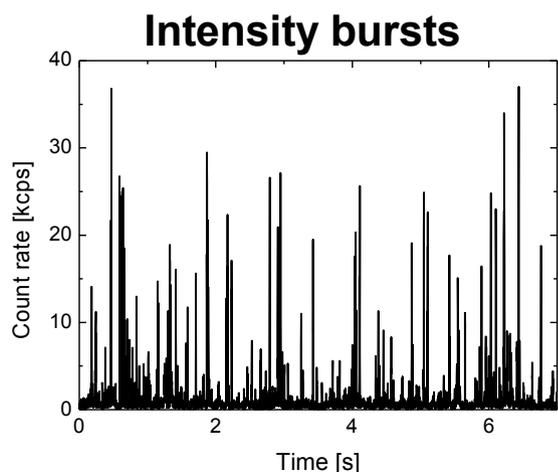

Molecular dynamics

- Conformational dynamics
- Binding kinetics
- Protonation dynamics / equilibrium
- FRET

Principle of Fluorescence Correlation Spectroscopy

Diffusion of a single molecule through the laser focus

$$G(\tau) = \frac{\langle \delta F(t) \cdot \delta F(t+\tau) \rangle}{\langle F(t) \rangle^2} = \frac{1}{V_{eff} \langle C \rangle} \cdot \frac{1}{1 + \frac{\tau}{\tau_D}} \cdot \frac{1}{\sqrt{1 + \kappa^2 \cdot \frac{\tau}{\tau_D}}}$$

$G(\tau)$ = Autocorrelation function
 τ = Correlation time
 $F(t)$ = Fluorescence at time t
 V_{eff} = Effective volume
 $\langle C \rangle$ = Concentration
 τ_D = Diffusion time
 $\kappa^2 = z/xy$ – Focus extention

Curve fitting:

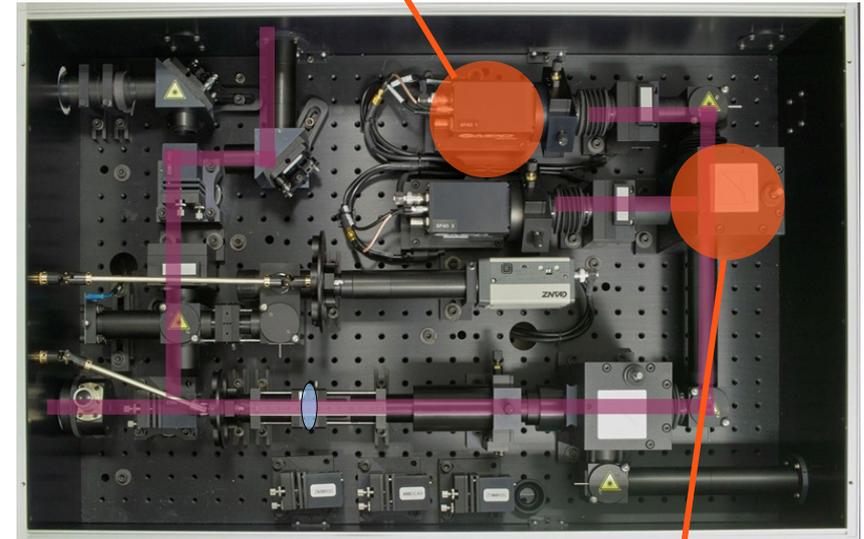

number of molecules in the focal volume → (+ focus size) → molecule concentration
 diffusion time through focus → (+ focus size) → diffusion coefficient

Limitations of FCS with cw Excitation

Autofluorescence + background
in the same spectral region
→ change the extracted amplitude
= concentration

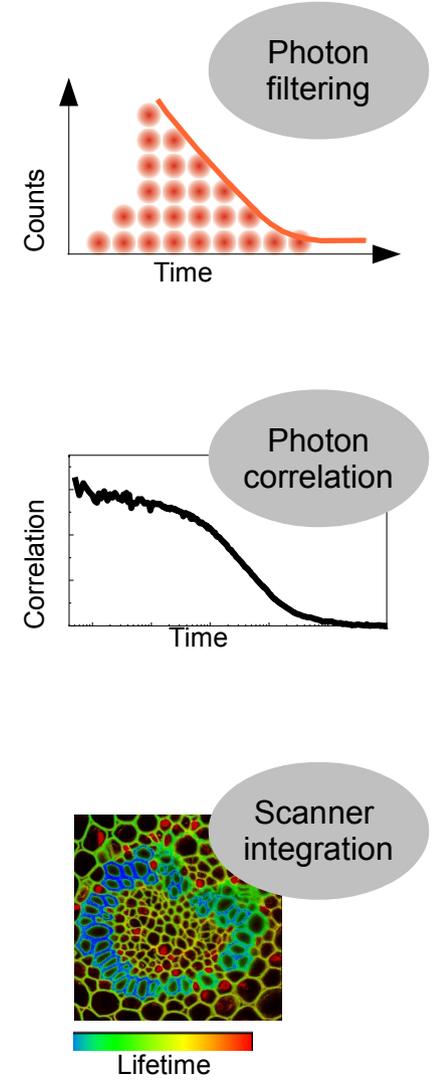

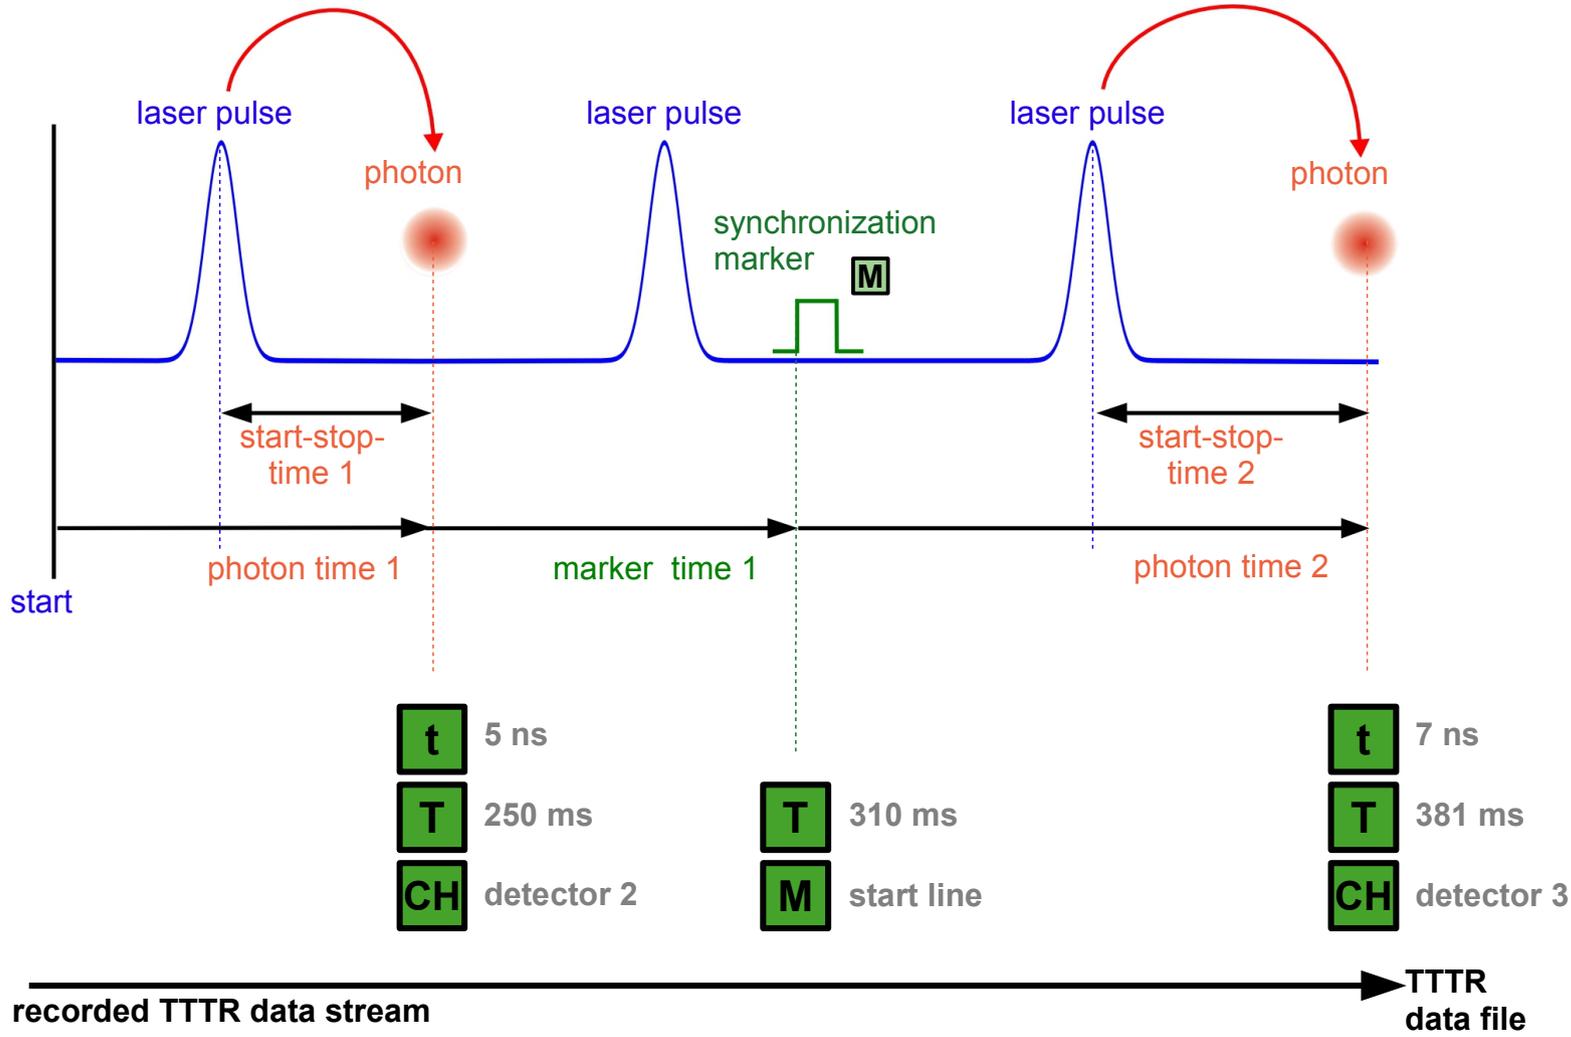

FCCS with dual colour excitation:
→ **different excitation volumes**
and perhaps positions
→ difficult to be calibrated and to be
described with a fit function

SPAD afterpulsing adds a fluctuating component
in the μs regime

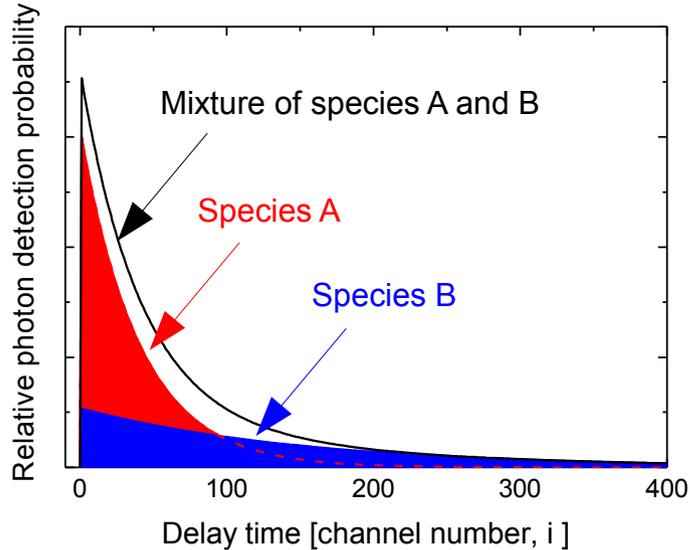

Dual colour FCCS:
spectral crosstalk
→ adds a wrong
cross correlation

Time-Tagged Time-Resolved (TTTR) Single Photon Detection Allows for FLCS

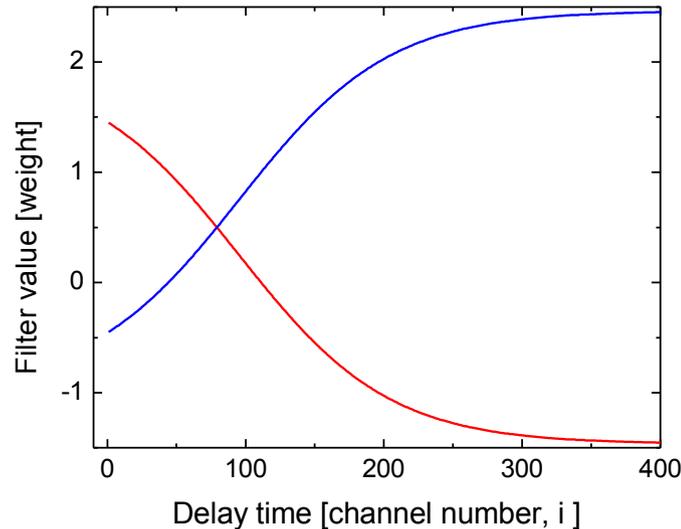

Principles of FLCS

Fluorescence lifetime histograms

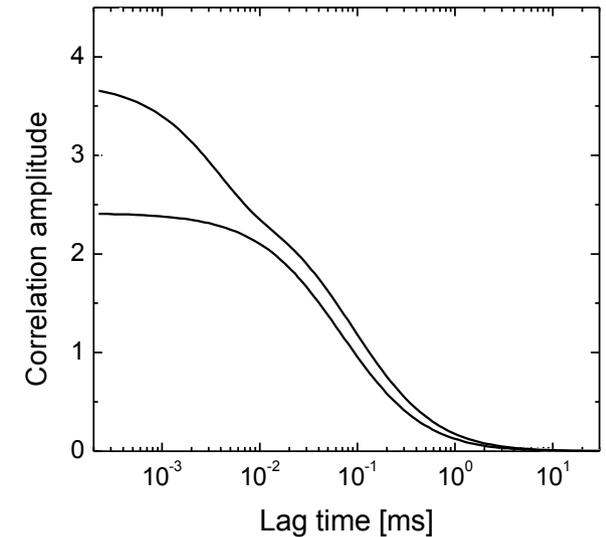

Photons most likely emitted by A Photons most likely emitted by B

Filter functions ("weights")

Separated FCS curves for species A and B

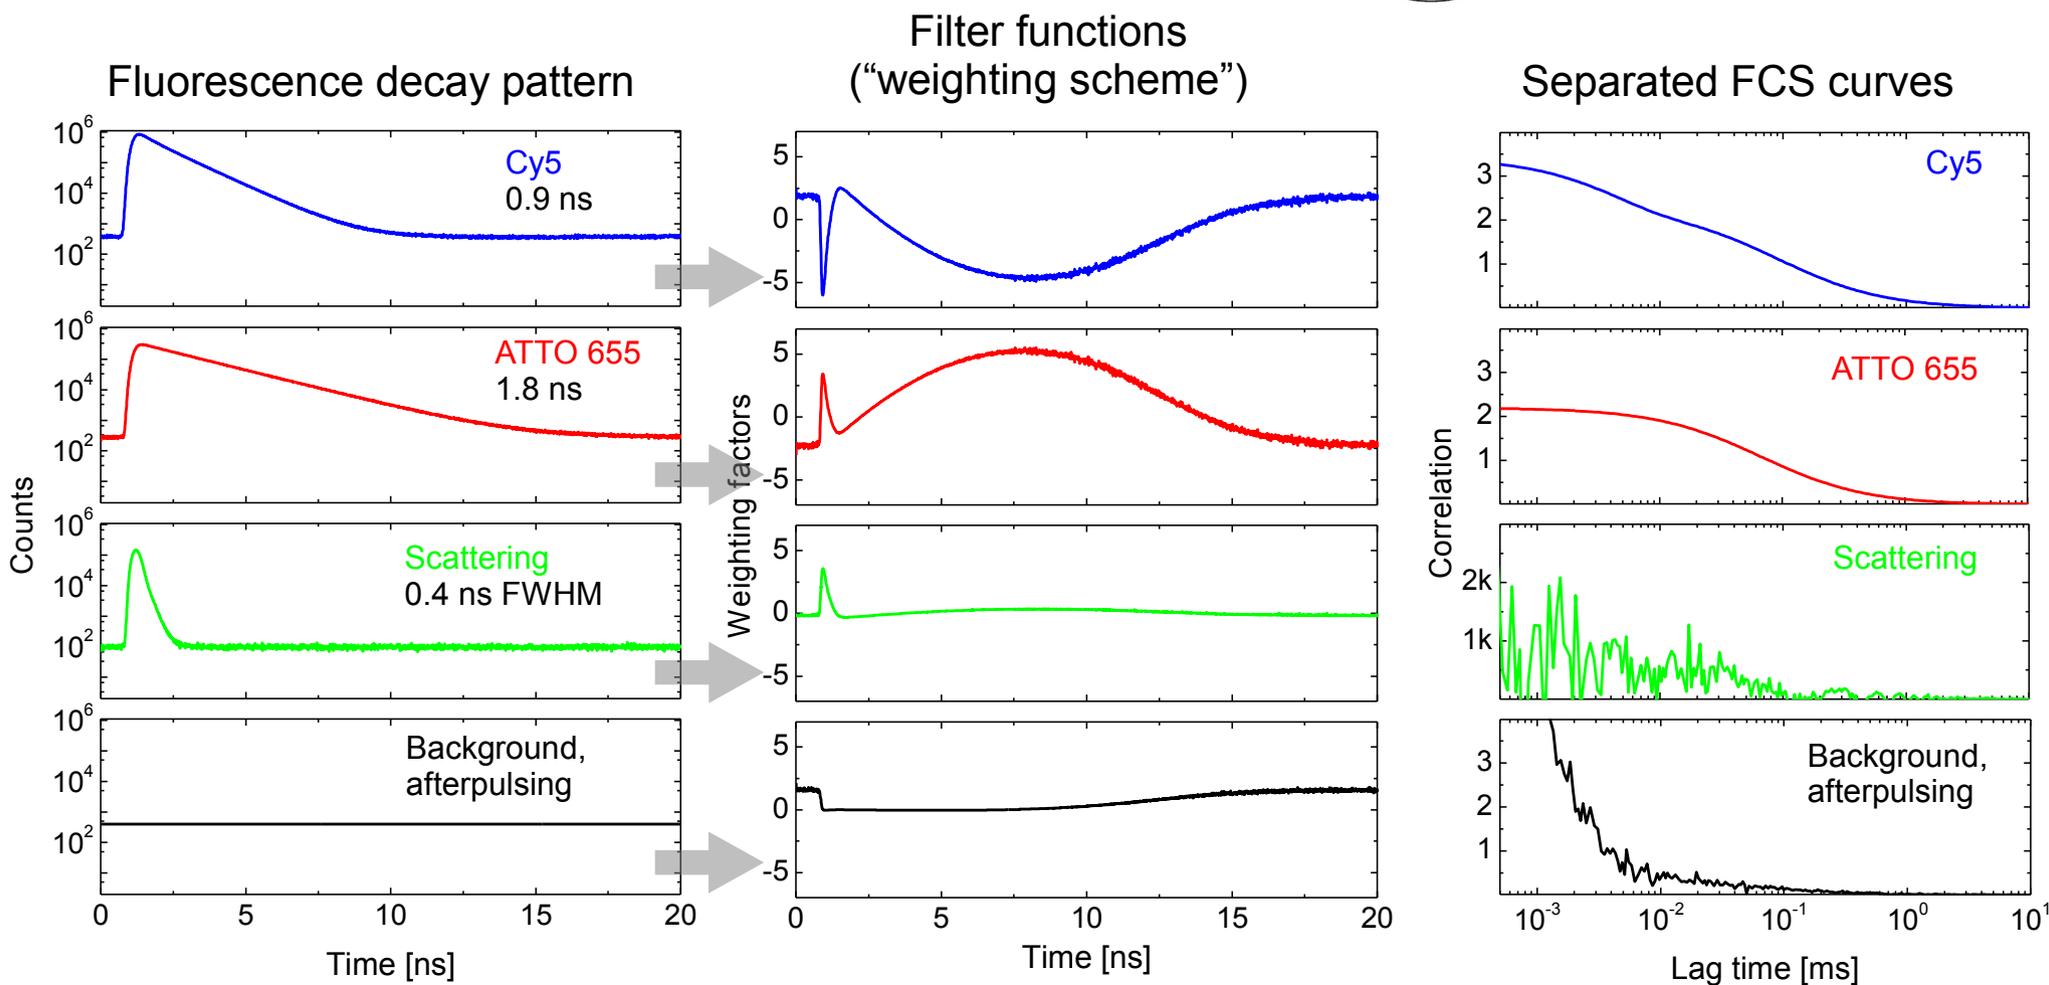

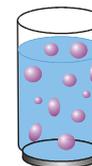

➔ Separated FCS curves for different species

- Removal of background
- Removal of afterpulsing
- More accurate results for concentrations and diffusion constants
- Separation of different fluorescent species

(1) Separation of Different Fluorescent Species with FLCs: Unmixing of 4 Components

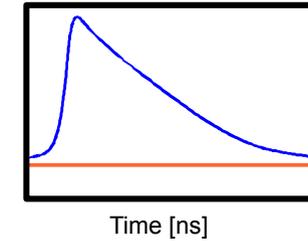

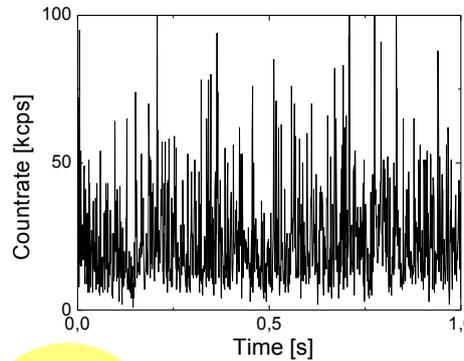

Equimolar mixture of **Cy5** and **ATTO 655**:

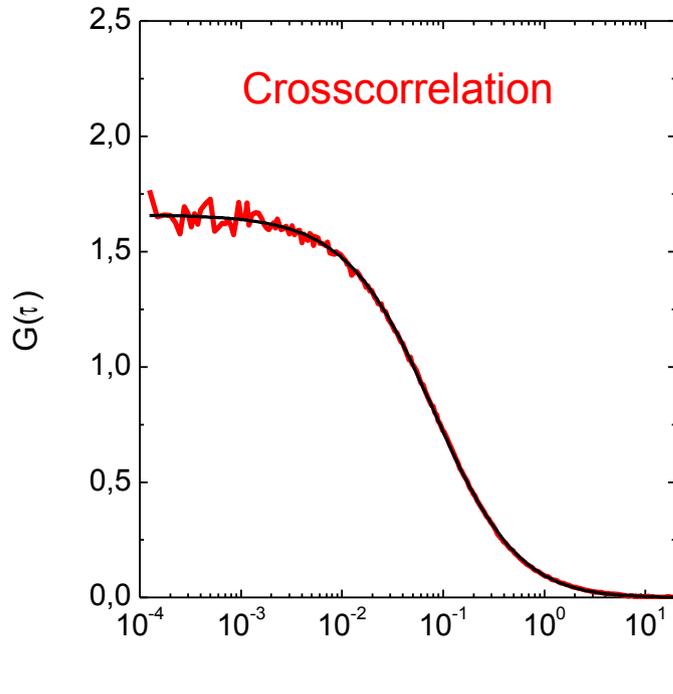

Graphs courtesy of Steffen Ruettinger, former member of PTB, Berlin, Germany

(2) FLCS to Eliminate Detector Afterpulsing

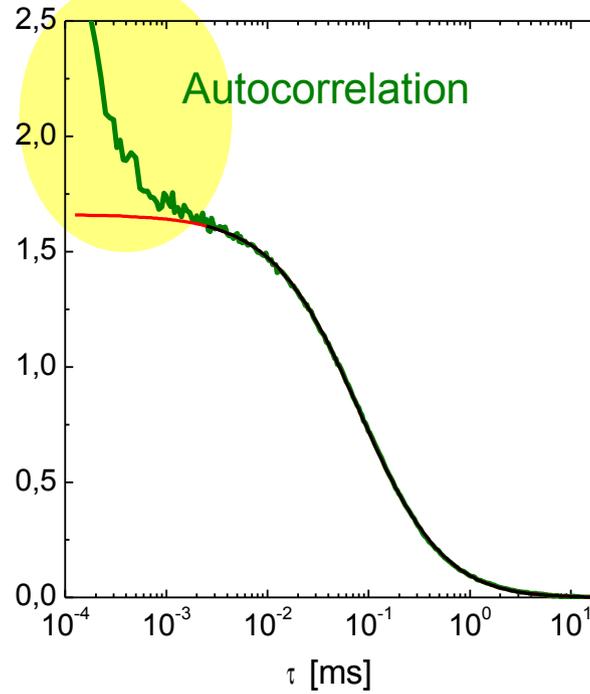

high fluorophore concentration
(ATTO 655 in water $c = 1 \text{ nM}$)
low background contribution

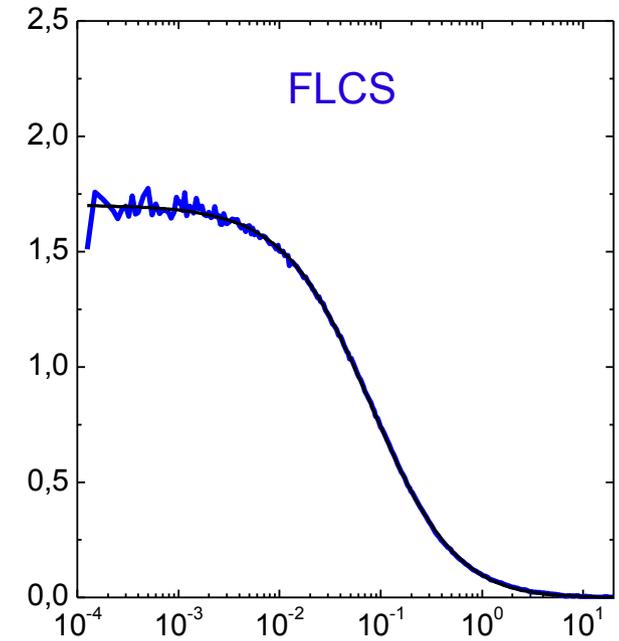

SPAD
afterpulsing

+ not influenced by detector
afterpulsing

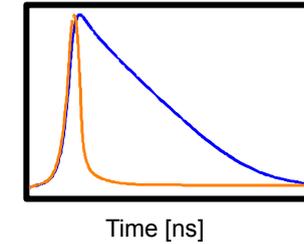

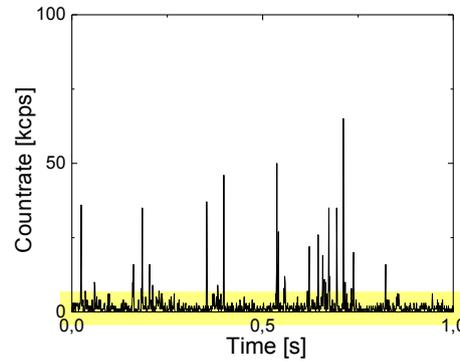

+ only 1 detector necessary
- afterpulsing

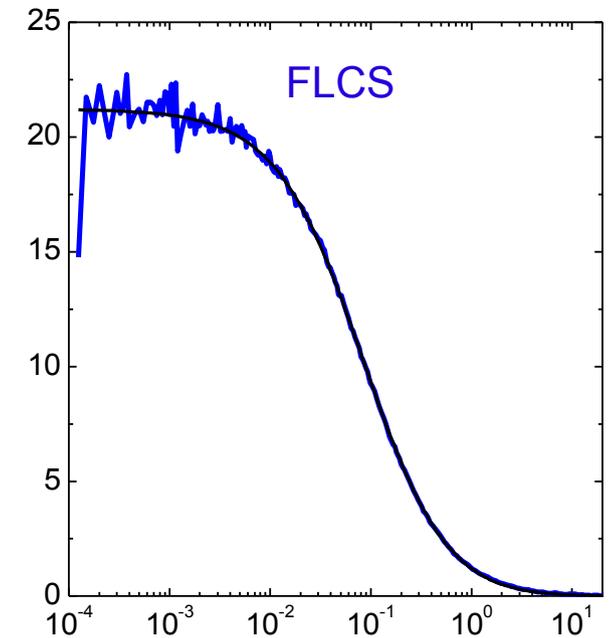

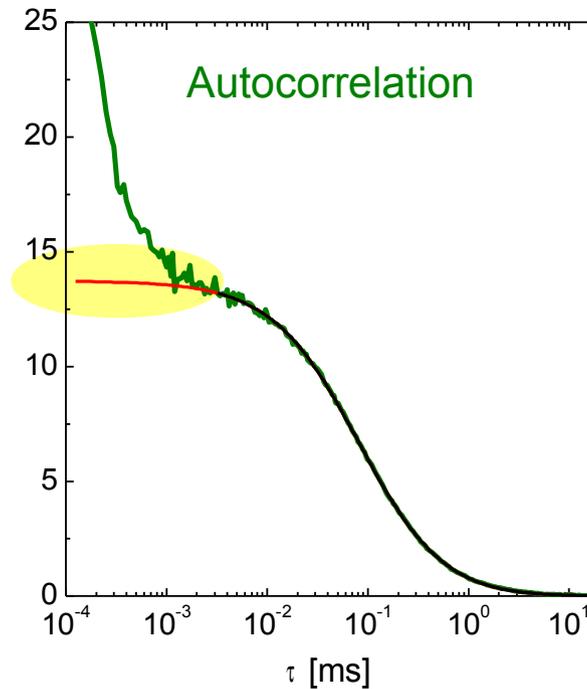

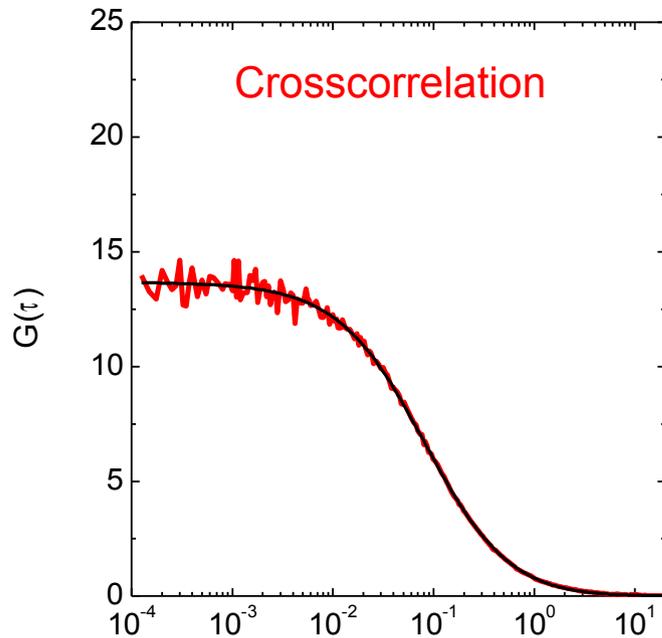

+ only 1 detector necessary
+ not influenced by detector
afterpulsing

(3) FLCS to Extract Accurate Concentrations

low fluorophore concentration
(ATTO 655 in water $c = 0.05 \text{ nM}$)
strong background contribution

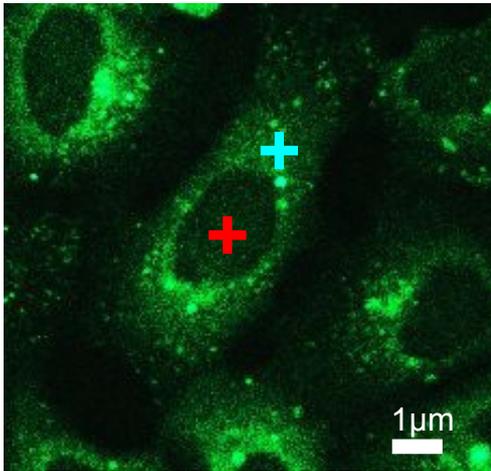

Scattered
excitation
light

+ $\langle N \rangle$ background corrected
→ accurate concentration

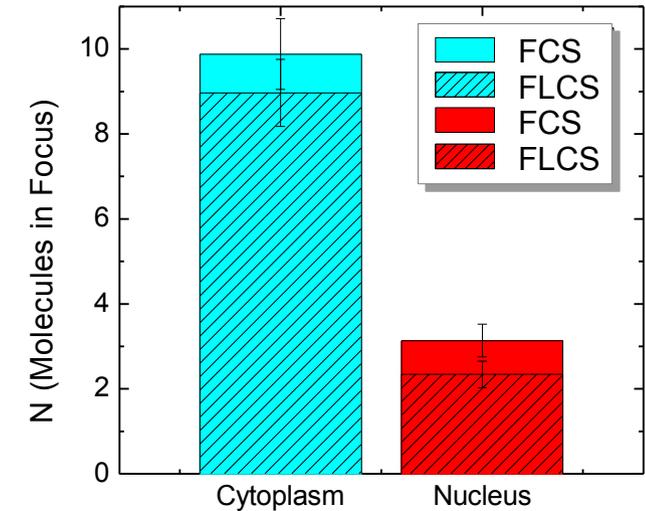

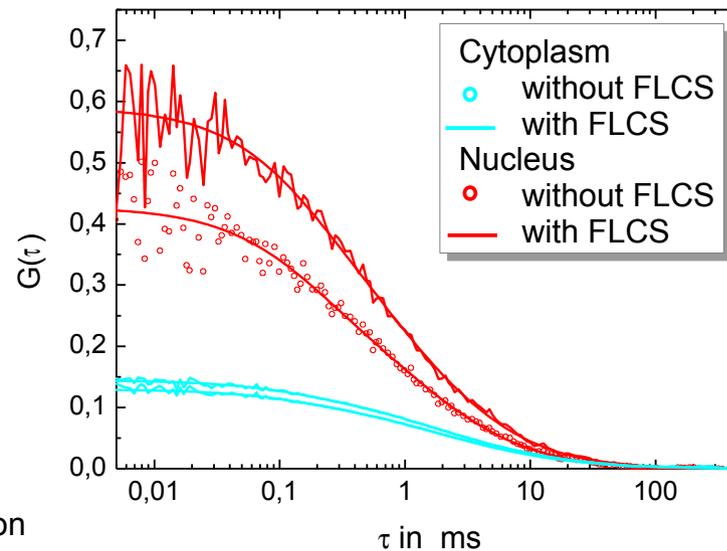

Concentration Measurements *in vivo*: GFP-tagged Proteins in Living Cells (Example)

ER293-cells with constant expression of GFP-Ago2

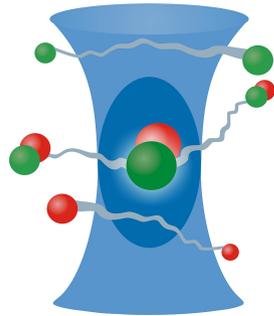

Excitation: 470 nm, 32 MHz
Emission: 520/40 band-pass filter
Objective: C-Apochromat 40x 1.2 W
10 curves with 30 s acquisition time are averaged
LSM Upgrade Kit

- Concentration of GFP-Ago2 can be determined in different cellular compartments.
 - FLCS removes background contributions.
- more accurate concentration determinations

Studying Molecular Interactions with Fluorescence Cross Correlation Spectroscopy (FCCS)

diffusion of molecules with 2 fluorescent labels through the laser focus

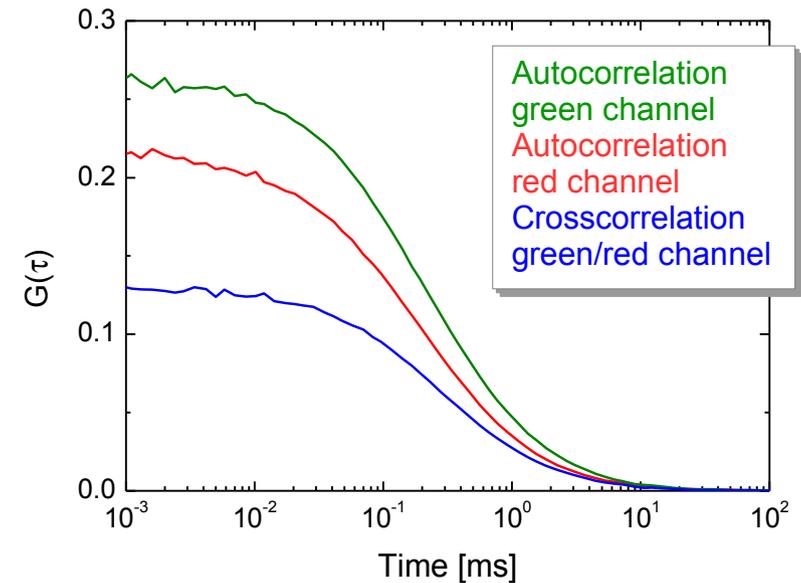

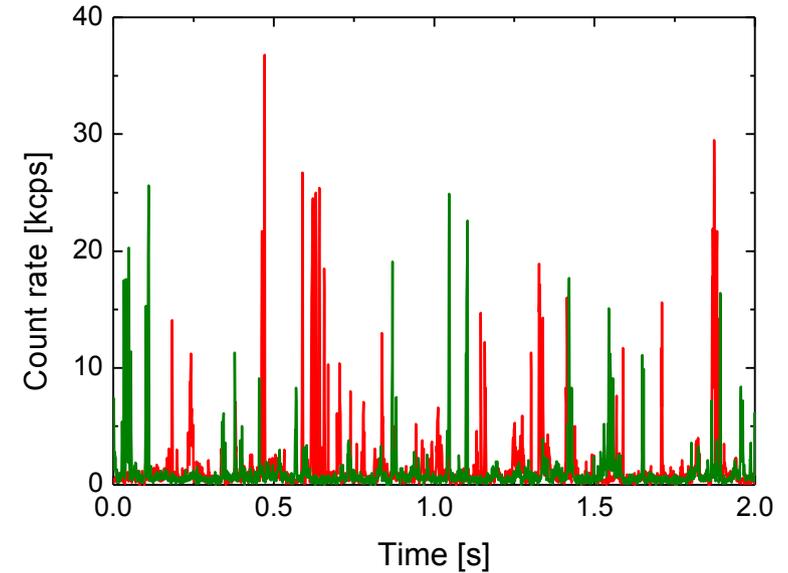

$$\langle C_{gr} \rangle = \frac{G_x(0)}{G_g(0) \cdot G_r(0) \cdot V_{eff}}$$

- $\langle C_{gr} \rangle$ = concentration double labeled species
- $G_g(0)$ = Amplitude autocorrelation green channel
- $G_r(0)$ = Amplitude autocorrelation red channel
- $G_x(0)$ = Amplitude Crosscorrelation
- V_{eff} = effective volume

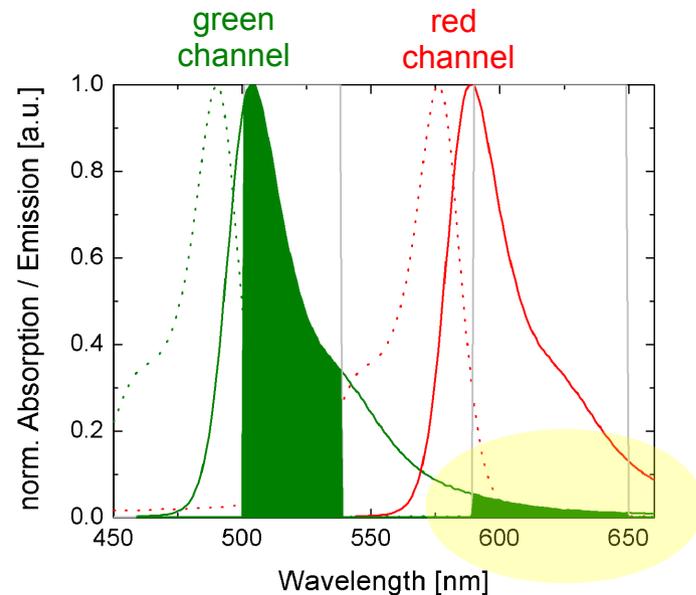

Autocorrelations **green channel** / **red channel**
 → molecule concentration **green** / **red** molecules

Crosscorrelation
 → concentration of double labeled species

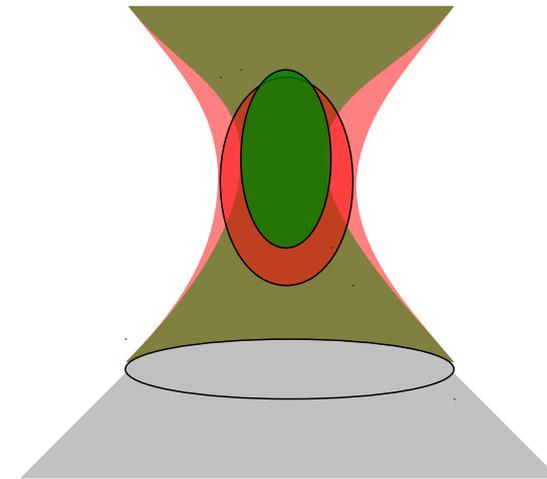

Intensity bursts in two spectral channels

Limitations of Dual Color FCCS: Spectral Crosstalk and Excitation Volumes

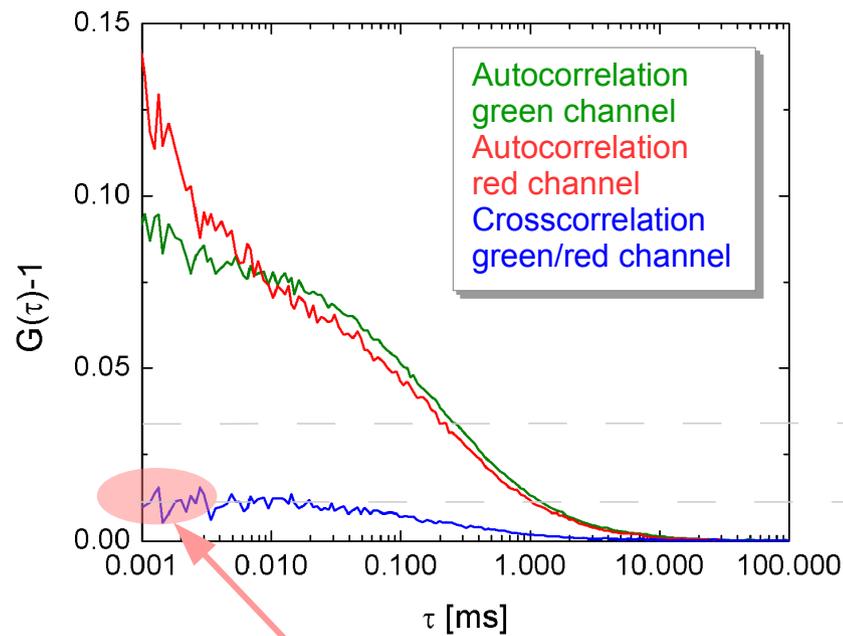

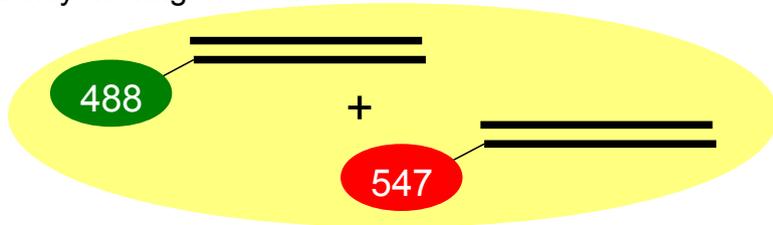

- Emission Spectra are usually broader than the *spectral window* of the detection channels.
- Especially the **green dye's emission** spectrum reaching into the red dye's detection window results in **spectral bleedthrough**.
 - Spectral bleedthrough causes a *false positive* crosscorrelation.
 - Necessary is a *negative control*.

- Focus size depends on the *excitation wavelength*.
- Additionally, imperfections of the optics & alignment can cause a *non – perfect overlay* of the different colors.
 - The overlapping (effective) volume needs to be *calibrated*.
 - Necessary is a *positive control*.

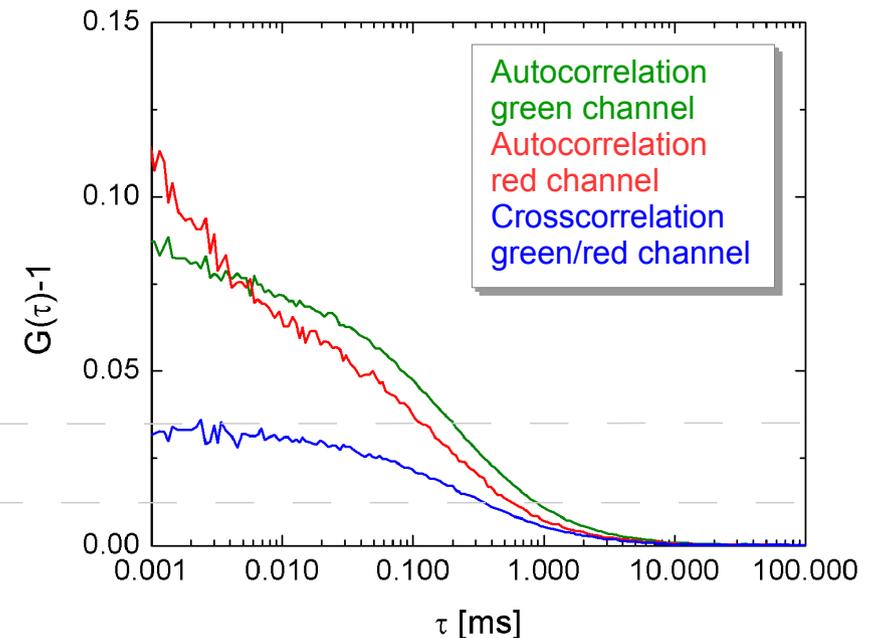

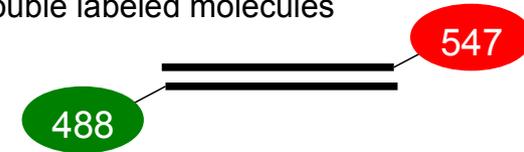

Calibration Measurements using Dual Color FCCS (without Lifetime Analysis)

independently moving molecules

False positive crosscorrelation
due to spectral bleedthrough

double labeled molecules

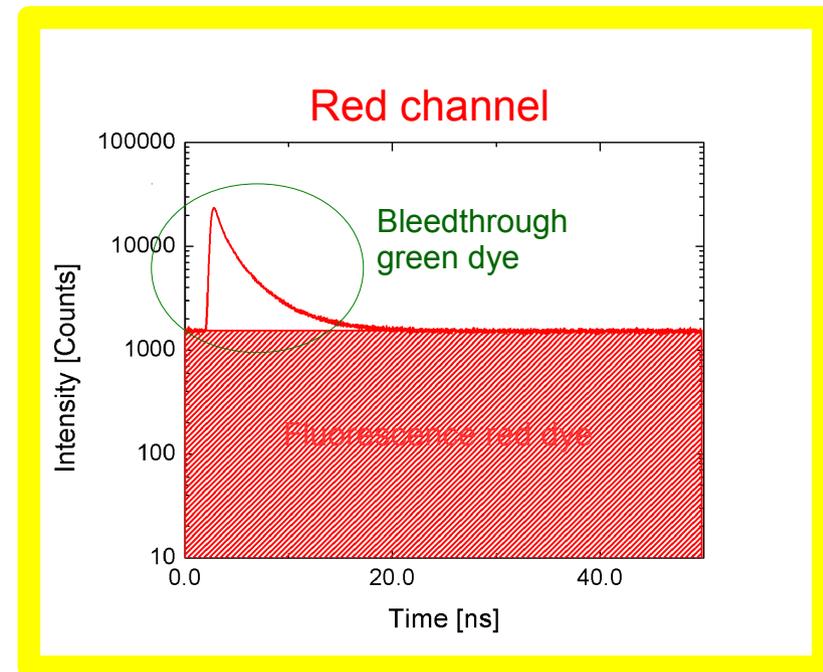

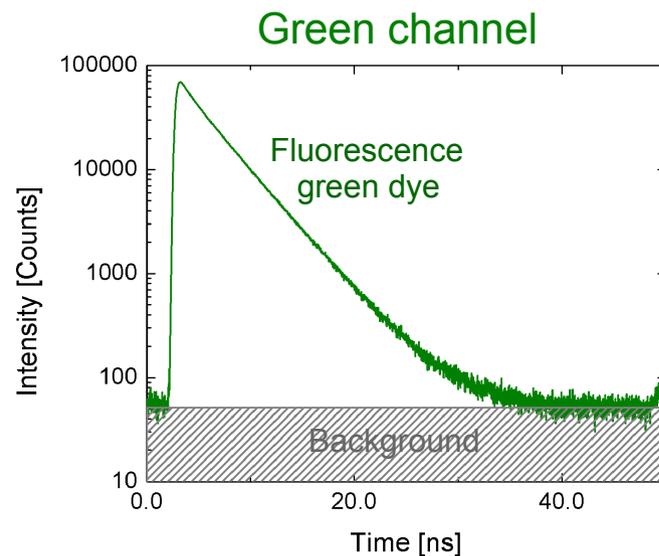

Sample: In vitro fluorescence crosscorrelation standard;
(FCCS standard) 488-543 nm from IBA
Data acquired with: LSM Upgrade Kit
 $\lambda_{\text{Exc 488-dye}}$: 485 nm, 20 MHz, $\lambda_{\text{Exc 547-dye}}$: 559 nm, cw
UPLAPO 60x, NA 1.2
Emission bandpass: Det. 2: HQ520/40, Det. 1: HQ620/60
DM488/559/635 + 570 nm dichroic

Sample courtesy of IBA, see:
http://www.iba-lifesciences.com/FCCS_Standards_Products.html

FLCCS: Fluorescence Decay based Crosstalk Identification

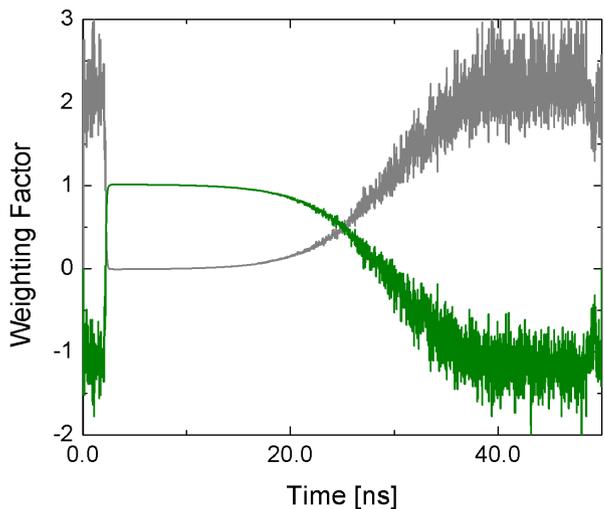

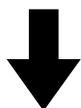

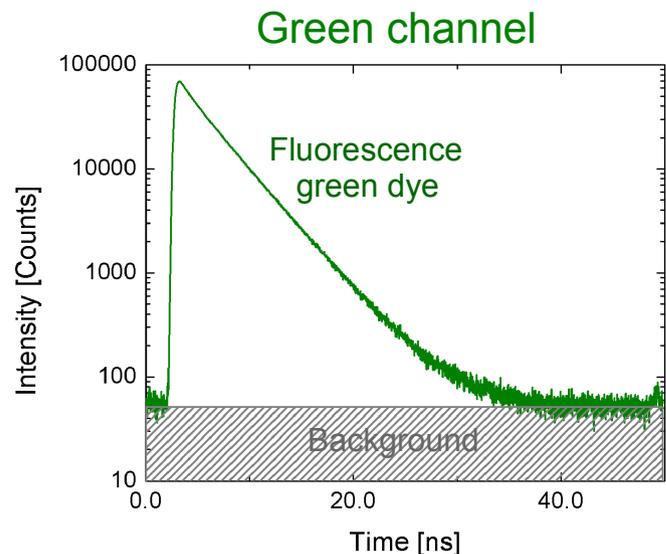

- *Idea*: Excite the samples with a *pulsed 485 nm* and a *cw 559 nm* laser.
- The fluorescence decay pattern in respect to the laser pulse is very distinct in both channels:

Sample: In vitro fluorescence crosscorrelation standard;
(FCCS standard) 488-543 nm from IBA
Data acquired with: LSM Upgrade Kit
 $\lambda_{\text{Exc 488-dye}}$: 485 nm, 20 MHz, $\lambda_{\text{Exc 547-dye}}$: 559 nm, cw
UPLAPO 60x, NA 1.2
Emission bandpass: Det. 2: HQ520/40, Det. 1: HQ620/60
DM488/559/635 + 570 nm dichroic

Sample courtesy of IBA, see:
http://www.iba-lifesciences.com/FCCS_Standards_Products.html

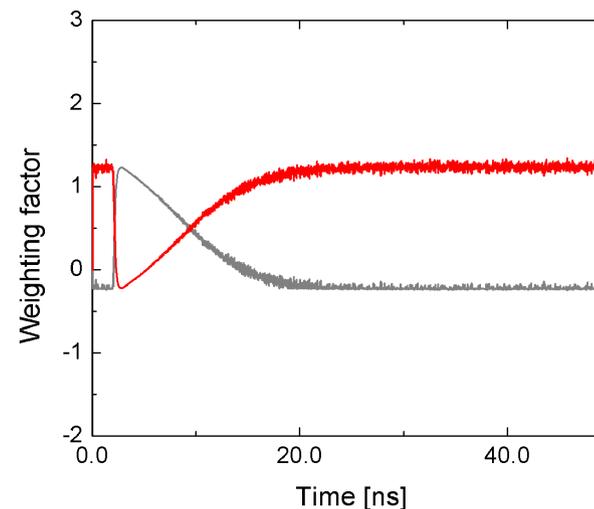

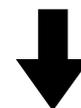

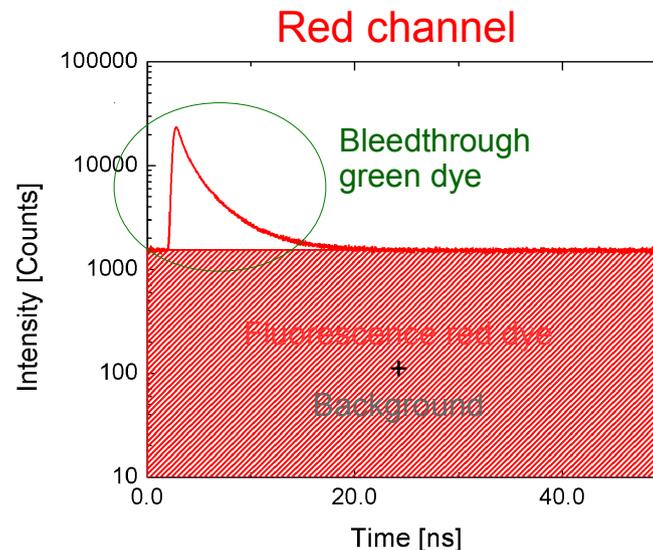

FLCCS: Fluorescence Decay based Crosstalk Removal

From decay pattern

calculate

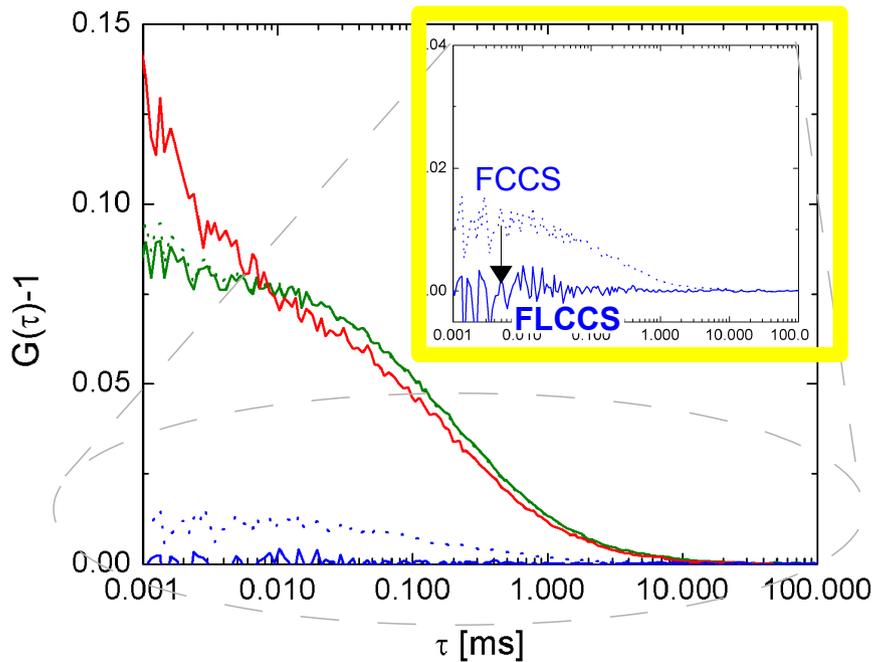

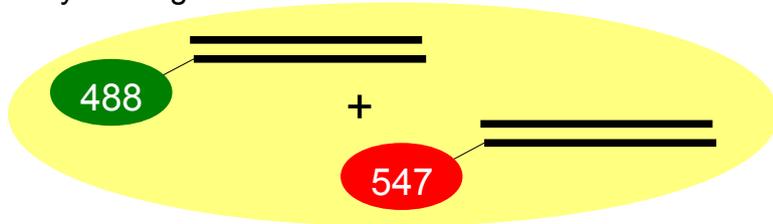

time – dependent
weighting factors
(FLCS filter functions)
for each spectral channel

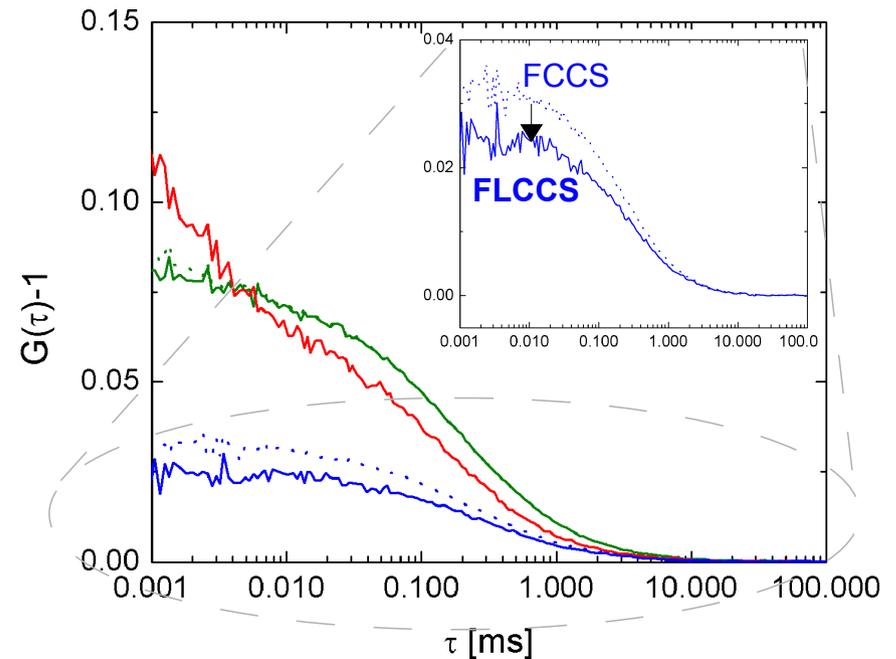

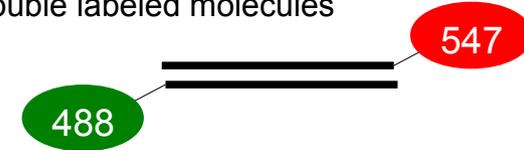

Sample courtesy of IBA, see: http://www.iba-lifesciences.com/FCCS_Standards_Products.html

FLCCS: Results for False Positive Crosstalk Removal

independently moving molecules

double labeled molecules

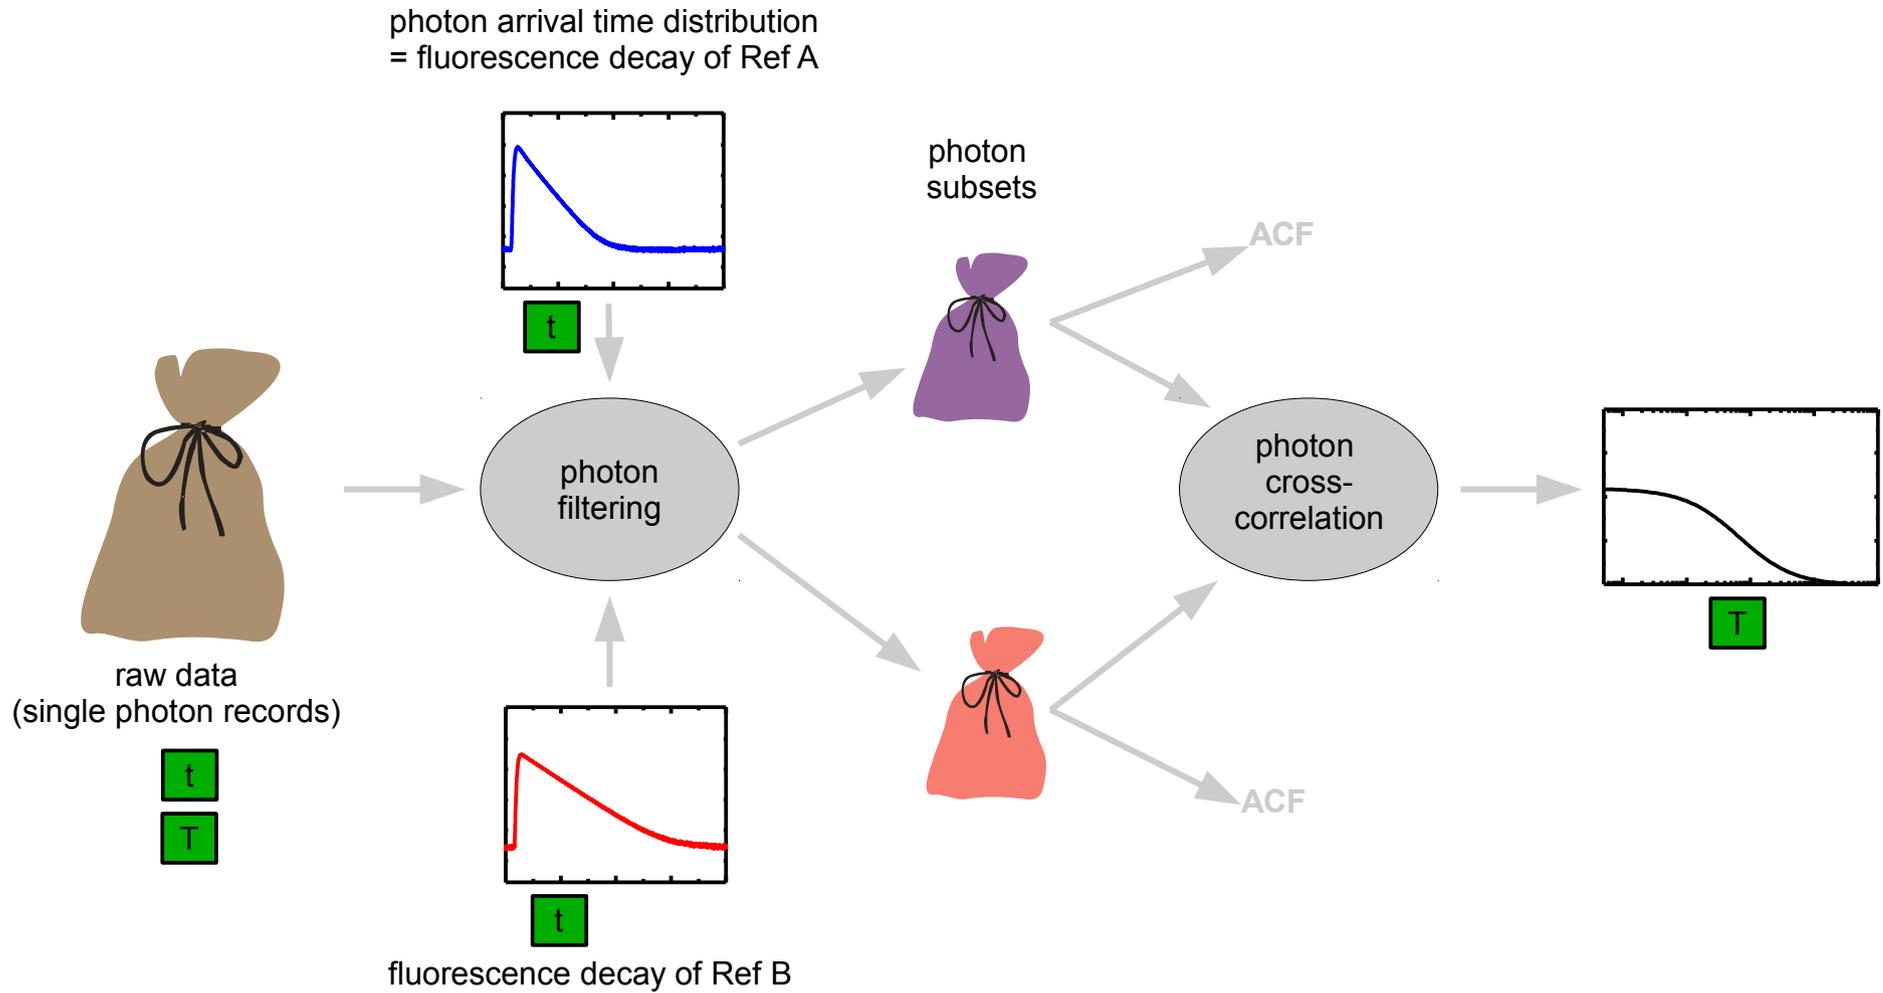

Sample:
 In vitro fluorescence crosscorrelation standard;
 (FCCS standard) 488-543 nm from IBA
 Data acquired with: LSM Upgrade Kit
 $\lambda_{Exc\ 488-dye}$: 485 nm, 20 MHz, $\lambda_{Exc\ 547-dye}$: 559 nm, cw

FLCCS almost *completely* removes
 false positive cross correlation
 caused by spectral bleedthrough

Sample courtesy of IBA, see:
http://www.iba-lifesciences.com/FCCS_Standards_Products.html

FLCCS Principle

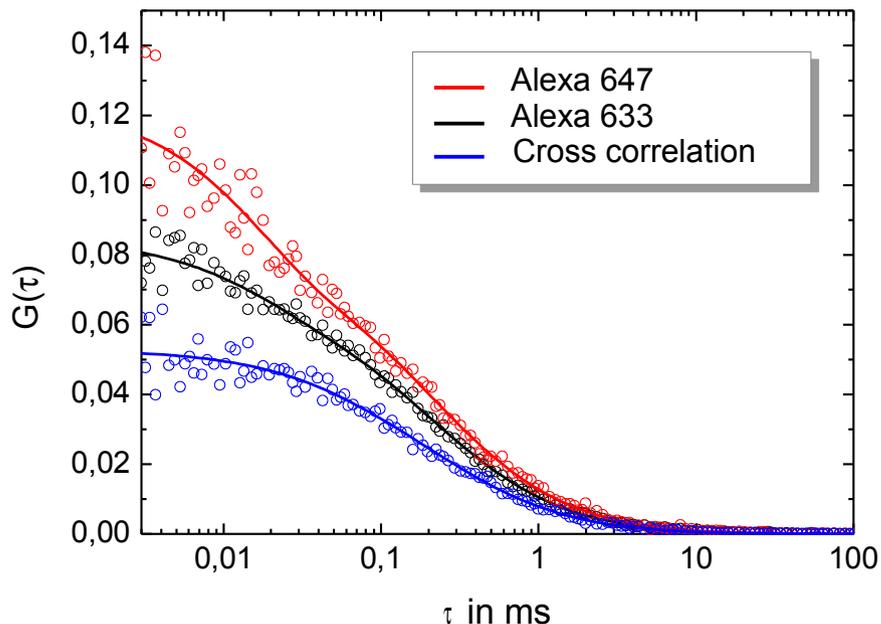

Example for FLCCS: Cross Correlation between Two Spectrally Inseparable Dyes

Alexa 633
 $\tau_{L2} = (3.13 \pm 0.03)$ ns
Emission max: 647 nm

Alexa 647
 $\tau_{L1} = (1.07 \pm 0.01)$ ns
Emission max: 668 nm

Diffusion times:

- dsDNA + Alexa 633: (222.4 ± 6.3) μ s
- dsDNA + Alexa 647: (215.1 ± 7.8) μ s
- dsDNA + Alexa 633 + Alexa 647: (244.4 ± 7.8) μ s

Crosscorrelation: (69.8 ± 2.0) %

**single color excitation
single channel detection**

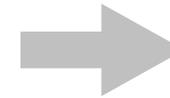

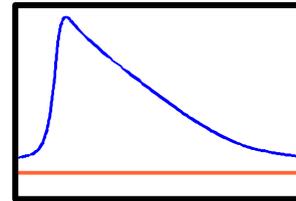

Sample: double stranded DNA oligonucleotide labeled with Alexa 633 and Alexa 647
Acquisition time: 10 min
Excitation: 635 nm, 20 MHz, 3.21 μ W
Emission: HQ685/70 band-pass filter
Objective: C-Apochromat 40x 1.2 W
LSM Upgrade Kit

Courtesy of M. Gärtner, P. Schwille, TU Dresden, Germany

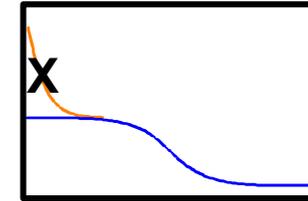

Summary: FLCS Applications

Remove **SPAD afterpulsing**
→ In a single channel setup!

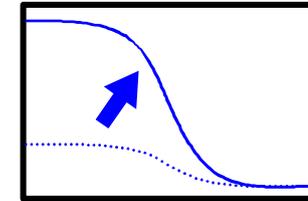

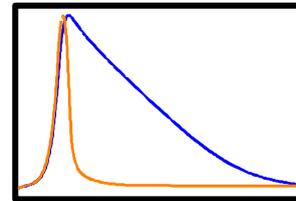

Decay pattern

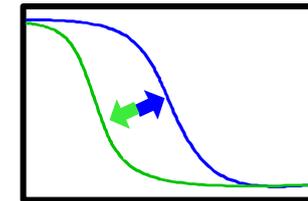

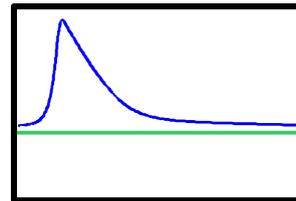

FCS curve

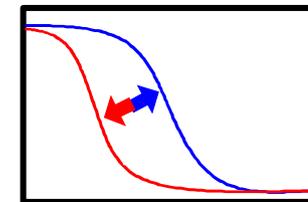

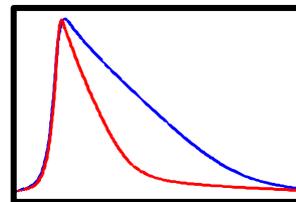

Remove **scattered excitation light and parasitic fluorescence**
→ quantitative results

Separate **pulsed** and **cw** excitation

Separate **species** with different lifetimes
→ but overlapping fluorescence spectra

Time [ns]

Time [ms]
